INTRODUCTION

Every election year, the students of Dr. Howard Christensen's sampling class have the opportunity to actually apply the methods, formulas, and concepts learned as they participate in a political exit poll survey. This "tradition" continued as the Statistics 534 class participated in conjunction with the Political Science Department to conduct exit poll surveys, interpret the results obtained, and make predictions, based on those results, as to the winners of statewide and national elections in 1988.

After reviewing data, methods and results from previous elections, sampling methods were defined, counties and voting places were chosen, and sampling rates and estimated turnouts were calculated. Statistical formulas were used to estimate the percentage of votes each candidate would receive, then a margin of error was calculated for those estimates.

This paper presents the work done by each of three groups from Dr. Christensen's class. Each group played a vital part in the project. The following pages discuss the activities of each in detail, showing actual formulas and explaining the procedures used.

SELECTION OF COUNTIES

Since a stratified sample was decided on, the first step was to divide the state into strata. Since the state is divided into three congressional districts, they were used as a basis for stratification. In addition, it was necessary that certain counties be included in the sample (certainty units). These also became strata. In total, four certainty units were chosen in District 1, four in District 3, and one in District 2 (the whole district/county). This resulted in 11 strata in our sample. Since District 2 consisted of just part of Salt Lake County, it was selected as a certainty unit. In the other two congressional districts, several counties were selected as certainty units because of the following: 1) students conducting the exit polls were attending universities in the county, 2) the population of the county represented a large proportion of the district, or 3) the voting record of the county was very representative of a significant minority in the state (e.g. Carbon County).

After certainty units were chosen, there were 12 counties remaining in District 1 and 10 counties remaining in District 3 from which to sample. From these counties, three more counties in each district were sampled. This selection process was based upon PPS methods (probability of selection proportional to size). The estimated turnout for each county

was used to create a running cumulative total (see Appendix I). Three numbers between 0 and the value of the cumulative total were sampled.

Once the counties that would be in the sample were known, this information was relayed to the estimation committee.

SELECTION OF VOTING PLACES

After the counties had been sampled, the projected voter turnout per county was calculated. Then, based on these projections, the number of voting places per county was calculated. The decision was made to sample 40 voting places from each of the three congressional districts. In order to calculate a within-county variance, at least two voting places needed to be polled in each selected county. A proportional allocation based on projected voter turnout was used to assign these 40 voting places among the selected counties in each congressional district. Therefore, more voting places were sampled from the counties with the larger projected turnout.

For example, in Congressional District 1, the total projected voter turnout of the counties selected was calculated. Then the proportion of the total turnout was calculated for each county. This gave the proportion of the 40 voting places that should be allocated to each county. If

there were less than two voting places allocated to any county, one voting place was taken from one of the larger counties so that all counties had at least two voting places to be polled. The allocation of voting places is given in the Table 1. The counties with the largest projected voter turnout, such as Davis and Weber County in Congressional District 1, received the largest number of voting places to be polled.

ESTIMATION OF VOTER TURNOUT

A group was assigned to estimate the 1988 voter turnouts for the various voting precincts in Utah. Within each of the counties sampled, voter turnouts for each voting place had to be determined from past data. Each person in the estimation group was responsible for entering the pertinent data for their assigned county or counties. Because the counties were different sizes, some students were assigned only a portion of a county while others were assigned three or four counties. This was done in an effort to balance the work load. November 1980 and November 1984 data from each county was used for estimation. This data was thought to be more representative of the current year because they were also Presidential election years.

METHODS OF ESTIMATION

A database was created of all the selected counties containing 1980 and 1984 voting information per precinct. The data included a code for the year (80 or 84), a county code, precinct numbers within the county, the total number of voters registered in each precinct, the total number of voters that turned out, and a code indicating the voting location for each particular precinct (see Appendix II). This information was compiled from county voting records. Since the precincts were realigned throughout the years in

many counties, additional precinct change information also had to be used. All the precincts were grouped according to the voting locations of the 1988 elections in an effort to track the same group of voters throughout these years.

A SAS program was then written to calculate the 1988 voter turnout per precinct. The algorithm used to determine this turnout is outlined as follows:

$$\frac{1984 \text{ Registered Voters}}{1980 \text{ Registered Voters}} = \% \text{ change}$$

$$(\% \text{ change}) \times (1984 \text{ Registered Voters}) = \begin{array}{l} \text{Estimated 1988} \\ \text{Registered} \\ \text{Voters} \end{array}$$

$$\frac{\begin{array}{l} 1980 \text{ Voter Turnout} \\ \hline 1980 \text{ Registered Voters} \end{array} + \frac{\begin{array}{l} 1984 \text{ Voter Turnout} \\ \hline 1984 \text{ Registered Voters} \end{array}}{2} = \begin{array}{l} \text{Estimated} \\ \% \text{ Voter} \\ \text{Turnout} \end{array}$$

$$(\text{Estimated 1988 Registered Voters}) \times \frac{(\text{Estimated } \% \text{ Voter Turnout})}{\text{Estimated 1988 Voter Turnout}} =$$

This algorithm was computed for each voting place within each of the counties sampled. The output of this program gave estimated 1988 voter turnout totals by voting place.

RESULTS OF THE ESTIMATION PROCESS

Because sampling rates are accelerated with underestimation, the intent was to estimate conservatively, since more people than expected would vote and all necessary data would be collected. Of the 13 counties sampled, seven were underestimates. Three of the remaining six counties were overestimates exceeding 10%. For example, the estimated total turnout for Uintah County was 6671 voters. The actual turnout was 7176. The estimated turnout was divided by the actual turnout, yielding .93. This number reflects the percentage of actual turnout estimated. Data for the remaining counties is found in Appendix III.

Over and underestimates could be attributed to lack of proper data or difficulties in assigning available data. For example, in Utah County, many precincts were combined from 1986 to 1988. (In 1986 there were 273 precincts in Utah County. This number was reduced to 146 in 1988). This caused difficulty in tracking voter turnout numbers from the 1980 and 1984 elections. Similar problems were encountered in other counties.

SAMPLING OF POLLING PLACES

After estimates for the 1988 turnout of each county had been calculated, polling places within these counties were

selected using PPS sampling. For any one county, estimates for the various locations were run through a FORTRAN program (alpha.for). This program gave a running total of the expected number of voters so that the final voting location had the cumulative total for the entire county. Next, the sample was taken using the running total so that polling places with a higher estimated turnout had a higher probability of being selected. This is similar to how the counties were selected. In a given county, the cumulative total was divided by the number of polling places to be sampled in that county. This number was used to select voting places based on a systematic use of estimated turnout. Next, a random number was selected between 0 and the cumulative total for the county. This was the random starting point and the first location that was selected. (See example in Appendix IV).

SELF WEIGHTING ESTIMATES

Proportional allocation was used in order to achieve self-weighting estimates. The estimates were self-weighting because in determining the number of elements to sample from each stratum, the stratum size was taken into account. Therefore, the larger the strata, the larger the sample size, and the sampling fraction is the same for each stratum. If

self-weighting had not been used, the sample size would be different for each polling place. In this case, it is not required to know the stratum from which each polling place comes. Therefore, the estimator is much easier to calculate.

For each strata, we calculated

- $n_{ijk} = N_{i..} (1/k) (1/p_{ij}) (1/c_1)$
- $n_{ijk} =$ the number of voters to be interviewed at each voting place in the strata
- $N_{i..} =$ the estimated voter turnout for the strata
- $(1/k) =$ the sampling fraction
 $=$ $\frac{\text{\# voters to approach in the entire state}}{\text{Estimated voter turnout for entire state}}$
- $p_{ij} =$ the number of polling places in county i
- $c_1 =$ # of counties sampled in strata i

An example using Uintah County is shown in Appendix V.

DETERMINING SAMPLING RATE

Using the n_{ijk} obtained from self-weighting, a sampling rate (k) was found by taking the estimated turnout for a given polling location and dividing by n_{ijk} . A random start was then chosen by selecting a random number (m) between 0 and the sampling rate. To conduct the sample, the interviewer started polling with the mth person leaving the polls and taking every kth person thereafter for the rest of the day. (See Appendix VI for polling places and sampling rates for the entire state.)

CONSTRUCTION OF GROUPS

In the case of survey data, a common way to estimate proportions and their variances is by using ratio estimation techniques, but the calculation of the variances using this method can be very cumbersome. To facilitate the calculation of the variances, an alternate method was used. This method involved placing each individual randomly into groups, calculating the proportions within each group and then taking the variance of those proportions using standard variance of means formulas.

In the case of the exit poll, there were 120 precincts sampled. The sampling rate at each precinct was based on a total sample of 20 taken from each precinct. There were to be 20 groups, one person from each precinct in each group. Once a person was randomly assigned to a group, they were to remain in that group for the rest of the day. This was done by creating a look up table that had two variables in it: the case ID matching those on the questionnaire, and the random group numbers assigned to each case ID. It was expected that if turnout estimation procedures were correct, 20 people would be sampled at a precinct but there were 30 questionnaires sent to a voting place in case of higher turnout than was estimated. In those instances, if the first three people were assigned to groups 18, 3, 7, respectively,

then the twenty-first, twenty-second, and twenty-third persons were assigned to groups 18, 3, and 7 respectively.

To do this, the raw data was read, the case IDs in the lookup table were matched with case IDs that were in the raw data, and the corresponding group number was assigned to the record. At this point, a permanent SAS data set (with group numbers and all questionnaire information) was saved; and all subsequent computer runs were done on this data set. Any case IDs that were not matched up were not put into the SAS data set. The look-up table that contained the groups did not keep any records that had been assigned out so that group numbers within precincts would not be reused except when more than 20 were sampled from a precinct. When new raw data came in, it was compared with the most recent look-up table, and then added to the permanent SAS data set.

HARDWARE/SOFTWARE

The analysis of the data was carried out on an IBM 9370 machine using SAS. See Appendix VII for program listing.

CALCULATION OF ESTIMATES

Utilizing the random groups, an estimate of the overall proportion and margin of error for those favoring a given response was obtained. PROC FREQ was used to generate cross-tabs, which gave the raw count and percent selecting a given

response to a question on the polling form. Margins of error were calculated only for questions on the survey relevant to an election or ballot result. PROC SUMMARY was used to obtain the proportion in each of the random groups favoring a candidate or ballot issue. PROC MEANS utilized these values to calculate sums of squares for overall proportion favoring. This value was then divided by the appropriate constant, in this case $n(n-1) = 20(19) = 380$ to obtain the variance of the proportion.

MARGIN OF ERROR CALCULATION

The margin of error for questions with essentially two possible responses was calculated by multiplying the standard error by 2. This simplified the following formula for calculating the variance of the difference between two random variables:

$$V(A - B) = V(A) + V(B) - 2*COV(A,B)$$

If someone votes for candidate A he cannot vote for candidate B, so there is a very high correlation between A and B. As a result, the variance of A will be almost exactly the same as the variance of B, and, the covariance will be negative with the same magnitude as the variance of A or B. This is shown in the following formula:

$$V(A - B) = V(A) + V(A) + 2*V(A) = 4*V(A) .$$

Taking the square root of the above result yields the margin of error.

In a case with three choices, (such as the gubernatorial race), the sample covariances had to be calculated. PROC SUMMARY and PROC MEANS were still used to calculate the variances for each of the three choices, but PROC CORR was used to obtain the covariances. PROC CORR is not recommended for doing this since the covariance must be extracted from the variance/covariance matrix produced.

PROBLEMS AND SUGGESTIONS

Although the exit poll was a success again this year, many problems were encountered along the way and on Election Day. Some of these include the following:

1. Too many people were involved in the gathering of county data. The process might have been simplified by making the design committee smaller and by adding a subgroup to the estimation committee. This group's responsibility would be the gathering of all information necessary for estimates and sampling.

2. Things could have run more smoothly if the data collection had begun sooner. County and polling place information could be collected at the beginning of the semester. Since the counties to be sampled will not be known, data could be collected on all counties. This extra

information would be valuable to future classes.

3. Many interviewers did not show up to their polling places. Stiffer penalties should be imposed on those who have committed to show up and do not. More emphasis on the importance of the interviewer would also help.

4. Many in the statistics class did not have the opportunity to actually go to polling places. With all the people who did not show up, there should have been ample opportunities for those who would have liked to participate.

5. Better interviewer training is needed. Too many interviewers were unprepared for the cold, darkness, and length of time they were supposed to poll. Much of this could have been averted if interviewers had read the instruction sheet prior to Election Day.

6. Many interviewers did not understand what information they were to call in. This could also be alleviated by better interviewer training.

7. There was a lot of negative publicity given to exit polls prior to Election Day. Positive press releases prior to the election might improve the respondent rate.

8. Many respondents complained about the length of the questionnaire and the small print. In other sampling classes, it is emphasized that larger print and white space results in greater acceptance of questionnaires.

9. Some data entry people complained about the lack of phone calls, while other people were on the phone constantly. If possible, a random distribution of calls should be sought for rather than the priority queue.

10. The computer programs required a lot of time and space to be run. A recommendation is to run the programs on a system separate from that used for data entry.

11. Because of problems encountered with the computer programs on Election Day, more dry runs are recommended.

APPENDIX I

APPENDIX III

Predicted vs. actual turnout for sampled counties

County	Estimated	Actual Turnout	Estimate as % of Actual Turnout
Box Elder	15563	16407	94.8
Cache	25508	27814	92.7
Carbon	8706	8557	101.7
Davis	59594	68139	87.5
Iron	8790	7820	112.4
Salt Lake	263156	275591	95.4
Sanpete	7907	6486	121.9
Sevier	7478	6211	120.4
Summitt	7025	6405	109.7
Tooele	10840	6837	(only 30 of 39 reporting)
Uintah	6671	7176	93.0
Utah	60633	87099	69.6
Washington	17159	16495	104.2
Weber	58387	61695	94.6

APPENDIX IV

Example of selection of polling places

The resulting output from the program alpha.for is as follows:

12	1	308	
12	2	434	
12	3	777	**
12	4	1421	
12	5	1610	
12	6	2268	
12	7	2259	
12	8	2625	
12	9	2828	
12	10	3710	
12	11	4109	**
12	12	4298	
12	13	4669	
12	14	5040	
12	15	5341	
12	16	5768	
12	17	6069	
12	18	6671	

Column 1 represents the county (in this case Uintah County), column 2 is the voting location, and column 3 is the running total of estimates. In this case two polling places were to be sampled; so a random number between 0 and 6671 was selected. This number was 765. This means that the third polling location was selected and by adding 3335.5 ($6671/2$) the 11th location was selected.

APPENDIX V

Example of self-weighting for Uintah County

$$n_{ijk} = \frac{N_{i..}}{(k) (p_{kj}) (c_i)} = \frac{42316}{(65.666) (2) (3)} = 107.58$$

$N_{i..}$ = total estimated voters in this strata

k = $\frac{591000}{9000}$ = estimated turnout for the state

p_{ij} = # of polling places sampled within each sampled county in the i th strata

c_i = # of counties sampled in the strata.

APPENDIX VI

APPENDIX VIII

Journals of time spent on project

Journal for Design Group

<u>Date</u>	<u>Activity</u>	<u>Man hours</u>
Sept 26-27	Organizing past data for use this year.	4.0
Oct 3	Group meeting with Dr. Christensen to determine group responsibilities.	3.5
Oct 5	Group meeting to determine certainty counties.	8.0
Oct 8	Organizing data for PPS sampling of noncertainty counties, and then sampling those counties.	6.0
Oct 11-14	Meetings with Political Science students to explain what we are doing.	8.0
Oct 17	Obtained data from Salt Lake (Capitol) for use of estimation group.	4.0
Oct 20-21	Meeting with Political Science students to touch bases on follow-up.	2.5
Oct 21	Proportional allocation of polling places.	8.0
Oct 25-28	PPS sampling of polling places within counties.	19.0
Oct 27	Follow-up meeting with Dr. Christensen.	1.0
Oct 28-Nov 1	Self-weighting and sampling rates.	30.0
Nov 2-7	Loose ends, and explanations to P. S.	5.0
Nov 2-7	Data entry training and interviewer training.	14.0
Nov 8	Exitpolling.	12.0
Nov 8	Data entry supervision.	24.0
Nov 18	Data entry supervision.	4.0
Dec 2-8	Report preparation.	26.0

		179.0

Journal for Voter Turnout Estimation Group

Meetings:

Oct. 3	.5 hrs
Oct. 17	.5
Oct. 18	1.0
Oct. 19	.5
Oct. 21	.5

	3.0

Getting county information, entering data:

Oct. 21 - Oct. 26 94.5 hrs

Computer program, data estimation:

Oct. 27 - Oct. 29 64.0 hrs

Data entry training:

Nov. 2 - Nov.3 8.0 hrs

Election Day:

Nov. 8	20.0 hrs	Data entry supervision
	8.0	interviewing
	14.0	watching KBYU,
	----	recording results
	42.0	

Post Election data entry:

Nov. 10 - Nov. 17 10.0 hrs

Writing group paper:

Dec. 2 - Dec. 7 5.0 hrs

TOTAL HOURS SPENT: 238.5 hrs

Journal for Computer group

Time: Hours worked X Number of People working = Total hours

- Oct. 14 Val, Daryl, and Jeff talked with Patty Collings.
Time: $2 \times 3 = 6$ hours
- Oct. 17 After class, discussed issues, and talked with Dr. Christensen about probability proportional to size sampling.
Time: $1 \times 4 = 4$ hours
- Oct. 18 Met with Dr. Magalby's TA's to discuss who is in charge of what, codes, responsibilities, # of terms, etc. Met with Kim Sullivan concerning questionnaire and random group indicators.
Time: $1 \times 4 + 1 \times 1 = 5$ hours
- Oct. 19 Met with Alan Long about data input responsibilities.
Time: $1 \times .5 = .5$ hours
- Oct. 20 Met with Larry Walters and Dr. Christensen about group indicators program.
Time: $1 \times 1 = 1$ hour
- Oct. 24 Discussed design, procedures to be used in SAS
Time: $1 \times 4 = 4$ hours
- Oct. 26 Made data entry sign-up lists for Dr. Christensen and Sister Collin's students to sign up for training and polling times.
Time: $2 \times 1 = 2$ hours
- Oct. 27 Calculated margin of error formulas. Tested formula on sample data set, determined how group numbers were to be created, and created initial SAS command file.
Time: $1.5 \times 4 = 6$ hours
- Oct. 28 Daryl talked with Dr. Christensen about variance, covariance for with three candidate race.
Time: $0.5 \times 1 = 0.5$ hours

Nov. 1-3 Data Entry Training Sessions with Kim
Sullivan
Time: 6 X 1 = 6 hours

Nov. 2-4 Each team member created SAS command file for
determining outcome of different races.
Time: 4 X 4 = 16 hours

Nov. 4 Created sample data set to test program.
Time: 1 X 19 = 19 hour

Nov. 4 Meeting with Dr. Magalby, Collings, Kim
Sullivan, and Brad to discuss final problems,
designs, and procedural methods.
Time: 1 X 3 = 3 hours

Nov. 5 Combined SAS command files with Political
Science department's files to create final
program.
Time: 11 X 4 = 44 hours

Nov. 7 Created the random group table and tested programs
with practice data.
Time: 1 X 2 = 2 hours

Nov. 8 Supervised and Troubleshoot Data Entry.
Correct program error on Margin of Error
output. Watch KBYU broadcast of election
results.
Time: 15 X 4 = 60 hours

Total Hours: 179.0 hours

Appendix IX

Final Results and Predictions

Dan Jones' Estimates:

Presidential

Bush	70
Dukakis	30

Senatorial

Hatch	70
Moss	30

U.S. Rep. District 1

Hansen	58
McKay	42

U.S. Rep. District 2

Owens	54
Snelgrove	46

U.S. Rep. District 3

Nielson	70
Stringham	30

Treasurer

Alder	55
Monson	44

Initiative A

Against	65
For	35

Initiative B

Against	66
For	34

Initiative C

Against	71
For	29

Other races were too close to report.
